## Texas Weekly Leading Index (Based on data through June 26, 2021)

Luis B. Torres

The Texas Weekly Leading Index increased considerably the week ending June 26 (Figures 1 and 2). The index has been gathering impetus and is pointing toward higher future economic activity as the reopening of the economy continues, and uncertainty regarding the pandemic dissipates due to increasing vaccination rates.

The index's increase was mainly due to a substantial decrease in the number of people filing for unemployment insurance and by a significant increase in the number of new business applications. The elevated number of new business applications is signaling strong future business activity.

Initial jobless claims in Texas decreased to 17,746 the week ending June 26, reaching pre-pandemic levels. In contrast, continuing unemployment claims increased to 191,381 the week ending June 19. Anecdotal evidence from service sector businesses points toward the lack of available applicants and generous unemployment benefits as major impediments in rehiring workers. To eliminate the incentive of remaining unemployed, Texas opted out of further federal unemployment compensation related to the COVID-19 pandemic on June 26, 2021. The measure will reduce minimum unemployment payments from \$19,240 a year to \$3,640 a year.

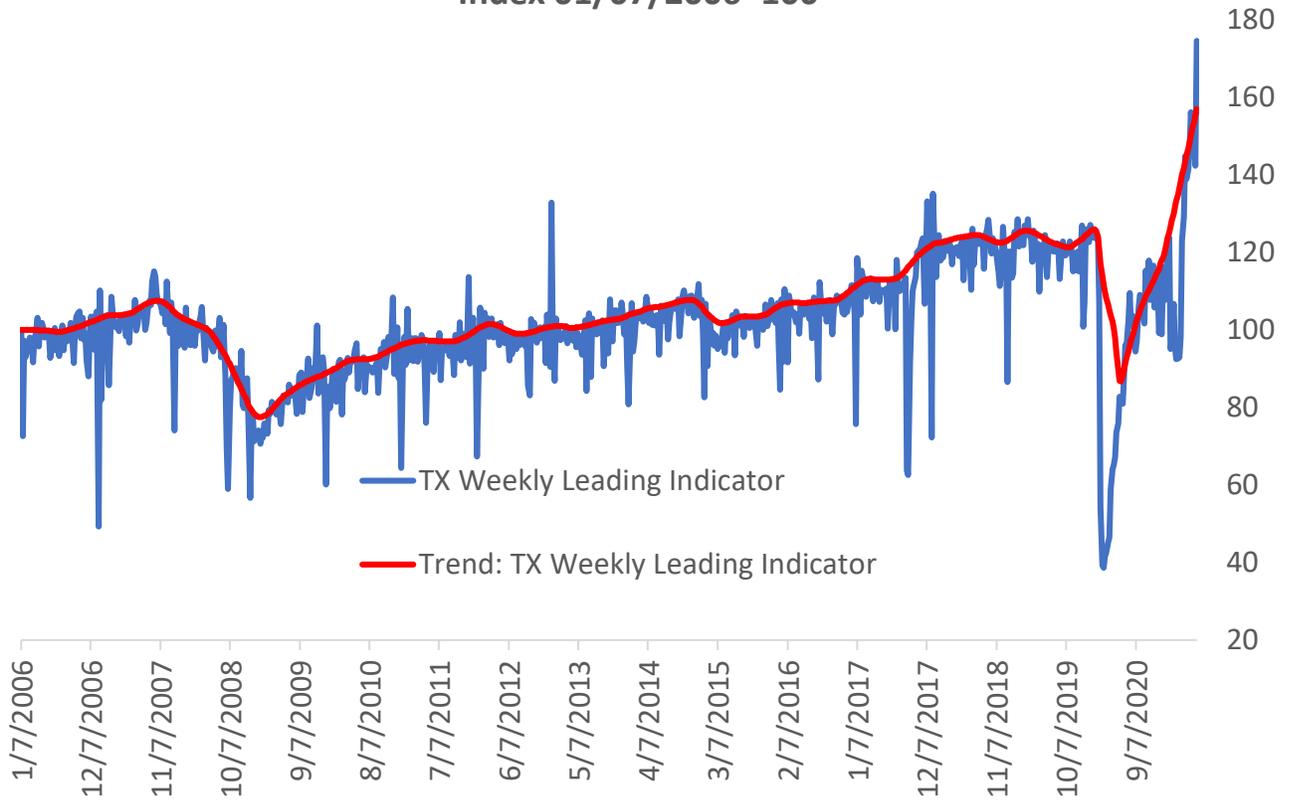

The outlook for the reopening and recovery of the state's economy improved as the number of new cases continues to fall up to the week ending June 26 (Figure 3). In addition, vaccination rates and herd immunity are increasing. This is benefiting consumer behavior, increasing business activity while reducing the number of layoffs going forward and allowing people to return to the labor force.

In addition, a decrease in the real rate for the ten-year Treasury bill (which continues to exhibit a negative return in real terms) combined with an increase in the real price of West Texas Intermediate (WTI) oil, contributed to the increase in the weekly index.

Based on both the Texas Weekly Leading Index and U.S. employment numbers from June, which increased by 0.6 percent over May, Texas nonfarm employment could increase 0.6 percent in June. If so, the Texas economy could gain around 75,000 jobs in June, reaching 12.6 million. In a span of 14 months the Texas economy could recuperate around 1,119,000 of the 1.4 million jobs lost between March and April.

Although this is becoming less likely, the rebound in Texas' economic activity could be hindered by possible upsurges in COVID-19 cases as economic and social activity increase. Further waves of infections can reverse increased mobility and spending, affecting the path to recovery.

## About This Report

The COVID-19 health crisis is unlike any crisis the economy has experienced before. The economy is currently going through a self-induced, sudden-stop to contain and stabilize the spread of the virus and save lives. The size of the economic shock will likely result in losses that overshadow losses from the 2008-09 financial crisis.

The Texas economy is not immune to the pandemic. In fact, the state's economy will be hit even harder than the world and the rest of the United States due to the simultaneous downturn in the oil industry.

This crisis has created a need for up-to-date economic indicators that can help forecast economic changes. The Texas Real Estate Research Center at Texas A&M University has constructed a high-frequency economic activity index for Texas that estimates the timing and length of future upswings and downturns on a weekly basis.

New weekly data series (also called high-frequency data) and new methodologies to seasonally adjust the data on a weekly basis have allowed for the development of weekly coincident and leading economic indicators. The Center has a successful track record in estimating monthly residential and nonresidential construction leading indexes for Texas. Both indexes have proven useful in signaling directional changes and forecasting key indicators like single family home sales, apartment vacancy rates, and commercial vacancy rates.

The Center evaluates economic data to determine:

- economic significance,
- statistical adequacy (in describing the economic process in question),
- timing at expansion and recessions,
- conformity to historical business cycles,
- smoothness, and
- currency or timeliness (how promptly the statistics are available).

However, the indexes do have some weaknesses. Underlying indicators are subject to revision, and while errors often cancel out across indicators, revisions impact the index and future monitoring of business cycles. In addition, although leading indicators often show the direction of a business cycle, they do not measure the magnitude of the change.

Even with these caveats, leading indicators are useful for measuring business cycles. Seven variables were evaluated for this report. Four (business applications, high-propensity business applications, business applications with planned wages, and business applications from corporations) are business market variables that are tied to state business activity. One variable, weekly initial unemployment insurance claims, is tied to state employment. Another, West Texas Intermediate (WTI) real oil price deflated by the all-urban consumer price index, is related to the oil industry. The last variable, the real ten-year Treasury bill estimated using same-period inflation expectations, represents the cost of credit in the economy.

Based on statistically reliable criteria, four variables were selected as economic activity leading indicators: business applications, initial unemployment insurance claims, real WTI oil price, and real ten-year Treasury bill. These variables demonstrated a significant leading relationship with Texas nonfarm employment. All other variables were found not to be statistically valuable or to perform below the business applications variable for the leading index.

Detecting turning points in any leading index on a month-to-month basis is difficult, because not all downturn (upturn) movements point toward recessions (expansions). It’s even more difficult to do on a weekly basis. The Center has converted the weekly leading economic activity index into a monthly leading index to evaluate its predictive usefulness.

Based on the National Bureau of Economic Research methodology, Texas nonfarm employment and the Dallas Federal Reserve Texas coincident indicator are used as references of peaks and troughs to measure the state’s business cycle (see table). This makes it possible to see if the weekly economic leading indicator can predict changes in Texas business cycles.

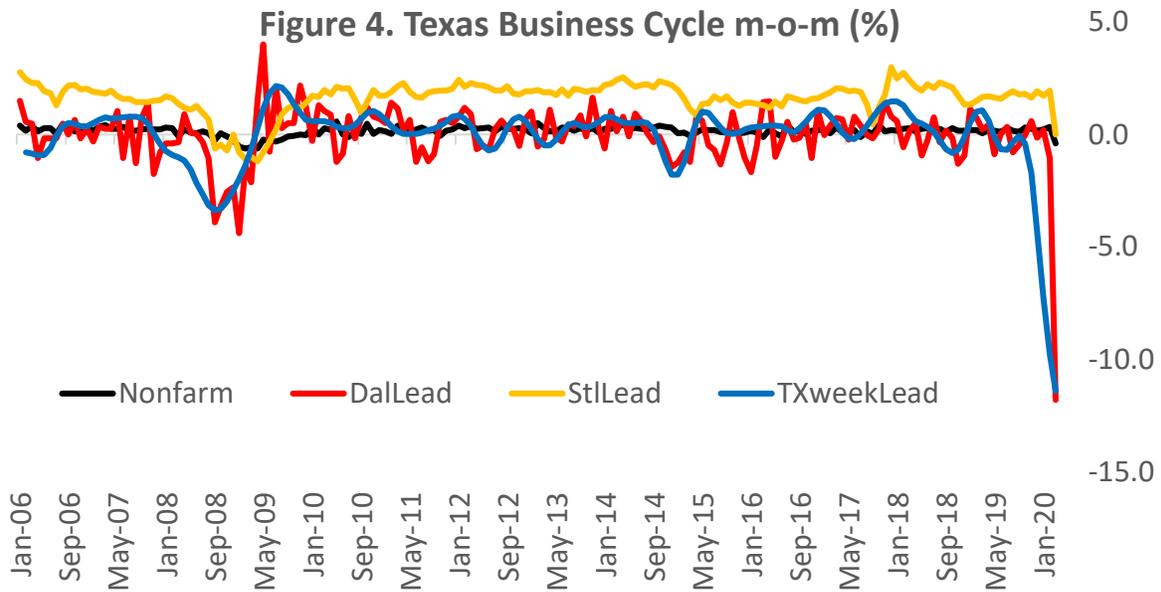

**Chronology of Texas Business Cycle**

	Peak Date	Trough Date	Months Contraction Peak to Trough	Months Expansion Trough to Peak
<b>Nonfarm Employment</b>	August 2008 February 2020	December 2009	17	123
<b>Dallas Fed Coincident</b>	August 2008	October 2009	15	126
<b>Dallas Fed Leading</b>	October 2007 January 2020	March 2009	18	131
<b>Texas Weekly Leading</b>	October 2007 February 2020	February 2009	17	133

Source: Bureau of Labor Statistics, Dallas Federal Reserve and Texas Real Estate Research Center at Texas A&M University

The Texas weekly leading index signaled a directional change in October 2007, 11 months before the prolonged downturn in employment that started in August 2008. Similarly, it signaled a recovery turning point in February 2009, 11 months before employment turned toward recovery in December 2009.

In addition, it predicted turning points and duration of expansion and contraction more accurately than another institution’s leading indicator—the one produced by the St. Louis Federal Reserve (Figure 4).

Note: Seasonally adjusted.

Sources: Bureau of Labor Statistics, Dallas Federal Reserve, St. Louis Federal Reserve, and Texas Real Estate Research Center at Texas A&M University

Overall, the leading index is regarded as a good indicator to predict turning points in Texas employment, even leading both the Dallas Federal Reserve’s coincident and leading indicators for the state’s economy.

One major problem in evaluating the index was the short time period. For a more accurate evaluation of business cycle relationships, it’s best to study the relationships over many business cycles. Because the predictive ability of the leading index was evaluated over a short time, it’s possible that the relationship might not hold in the future. Thus, the leading index for economic activity will be best evaluated based on its ability to lead Texas employment in the future. ❖
